Lab 2 Report

Name: Andreas Persson
Student ID: Andreas Persson 0486
Target Grade: Grade 3
Repo link: https://github.com/CeluneNyx/HTMLWebsite

List of features:

- Added Feedback form with Name, Email, Topic dropdown, comments and an optional website link inputs.
- Javascript Validation for every section of the form.
- Javascript Submit behavior
- A live character counter for the comments section of the form (Very unclear what you meant with "Keeping the written count understandable without color").
- Error messages and success messages when trying to submit the form.
- Input boxes turn red if invalid.
- A clear button that resets everything in the form.
- CSS to make the selected section get highlighted.

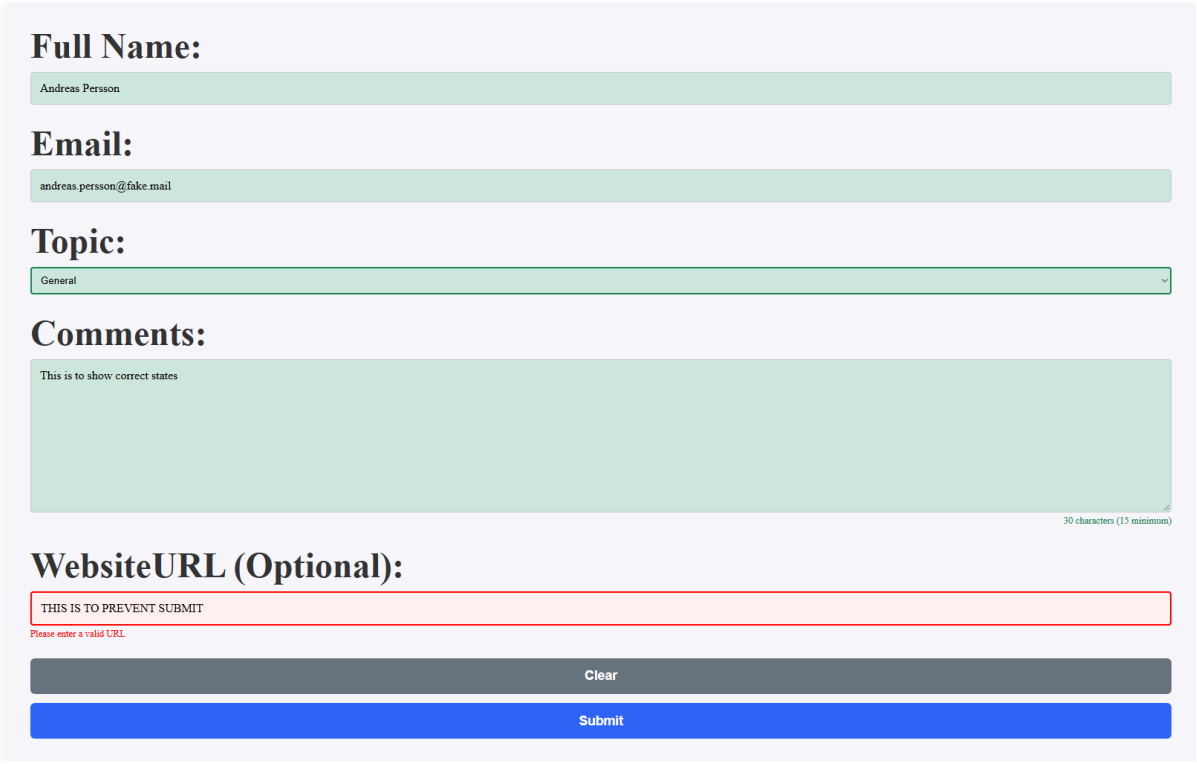

Picture evidence:

Picture of untouched form (Full Neutral state)

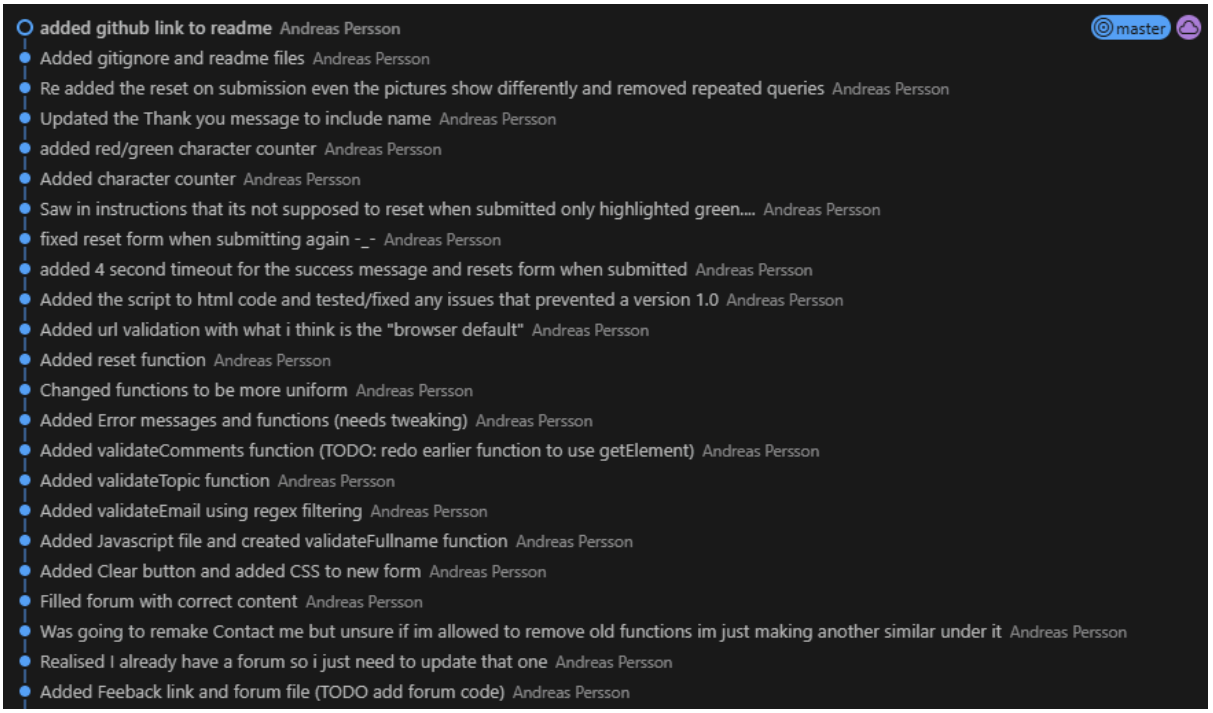

Picture of invalid state

Picture of correct state (except URL so it doesn't reset the form on submit)

Successful Submit with Thank you message

Github commits for lab 2

Code Explanation:

Main function for the form I would say include the validation functions:

- validateFullName()
- validateEmail()
- validateTopic()
- validateComments()
- validateURL()

and the resetForm() and showFieldError() functions.

As for the events they work by listening for a submit on the feedbackForm and as it picks up that event it executes the code which cancel the default submit response and instead run validation functions that check if a field is valid or invalid and marks it as one of those 2 then move on to the next validation function then after it has validated all the functions it checks if all the functions passed and if so it shows a submit message with the users name and resets the form and 4 seconds later the success message disappears.

Problem Solving:

The biggest problem I encountered was probably how to validate the email so it would match the correct format and after looking online I found regex but it confused the hell out of me which made me interested to understand it and solved it by learning basic regex coding.

Reflection:

I know the regex code pretty well because I needed to read about it for a bit so that would probably be fun explaining. Other than that pretty much any function.

My Git history shows where each addition of a function was added and changes to those functions but a few times I forgot to commit so sometimes more than 1 change got committed at the same time. Something that shows a lot was how the success submit was supposed to look, if the field was supposed to reset or stay. A lot of my functions also changed as I actually implemented them.

If I had one more development session i would probably test so every case does as it was intended and the website be bullet proof and if I really was committed to this website i would probably add a bit of Cybersecurity to the website (SQL injection protection).
